Abstract
Increasing atmospheric CO\textsubscript{2} concentration affects plant activities directly. In order to investigate the effect of CO\textsubscript{2} concentration, an experiment was conducted at Research Greenhouse of College of Agriculture, Shiraz University, Shiraz, Iran. In this research, the effects of increasing CO\textsubscript{2} concentration from 350 to 750 mg/L were studied on growth and yield of red bean (\textit{Phaseolus vulgaris}, cv. Naz) at four irrigation levels (1.2 FC, FC, 0.8 FC and 0.6 FC). In order to control CO\textsubscript{2} concentration, at the onset of the 4-leaf stage, pots were moved to wooden chambers covered with plastic. The results showed an average 15% decrease in evapotranspiration due to increasing the CO\textsubscript{2} concentration. Also the results indicated an increasing effect of CO\textsubscript{2} concentration on growth and yield of bean plants. Reducing the irrigation level to 0.6 FC caused the elevated CO\textsubscript{2} concentration not to have any significant effect (P<0.05) on growth and yield of the red bean. By increasing the CO\textsubscript{2} concentration, number of seeds/plant at FC and 0.8 FC irrigation treatments increased by 13 and 11%, respectively. Moreover, increasing CO\textsubscript{2} concentration caused 20% increase in total seed yield. Total dry matter increased about 15% at higher CO\textsubscript{2} level. The conclusion of this research was that increasing CO\textsubscript{2} concentration has significant effect on yield and reduction of evapotranspiration of red bean.
